A **network** is based on two sets – set of **nodes** (vertices), that represent the selected **units**, and set of **links** (lines), that represent **ties** between units. They determine a **graph**. A link can be **directed** – an **arc**, or **undirected** – an **edge**.

Additional data about nodes or links can be known – their **properties** (attributes). For example: name/label, type, value, ...

Network = Graph + Data

The data can be measured or computed,

Besides the graph, we need data to understand the network!

A *network* $\mathcal{N} = (\mathcal{V}, \mathcal{L}, \mathcal{P}, \mathcal{W})$ consists of:

- a *graph* $\mathcal{G} = (\mathcal{V}, \mathcal{L})$, where \mathcal{V} is the set of nodes, \mathcal{A} is the set of arcs, \mathcal{E} is the set of edges, and $\mathcal{L} = \mathcal{E} \cup \mathcal{A}$ is the set of links.

$$n = |\mathcal{V}|, m = |\mathcal{L}|$$

- \mathcal{P} *node value functions* / properties: $p: \mathcal{V} \rightarrow A$
- \mathcal{W} *link value functions* / weights: $w: \mathcal{L} \rightarrow B$

unit, actor – node, vertex
tie, line – link, edge, arc

arc = directed link, (a, d)
 a is the *initial* node,
 d is the *terminal* node.

edge = undirected link,
 $(c: d)$
 c and d are *end* nodes.

$$\mathcal{V} = \{a, b, c, d, e, f, g, h, i, j, k, l\}$$

$$\mathcal{A} = \{(a, b), (a, d), (a, f), (b, a), (b, c), (c, b), (c, c), (c, g)_1, (c, g)_2, (e, c), (e, f), (e, h), (f, k), (h, d), (h, l), (j, h), (l, e), (l, g), (l, h)\}$$

$$\mathcal{E} = \{(b: e), (c: d), (e: g), (f: h)\}$$

$$\mathcal{G} = (\mathcal{V}, \mathcal{A}, \mathcal{E})$$

$$\mathcal{L} = \mathcal{A} \cup \mathcal{E}$$

$\mathcal{A} = \emptyset$ – **undirected** graph; $\mathcal{E} = \emptyset$ – **directed** graph.

The R package igraph **doesn't support** the mixing of arcs and edges. A graph is either directed or undirected.

In most applications, an edge ($u: v$) can be replaced by a pair of opposite arcs (u, v) and (v, u).

Properties of nodes \mathcal{P} and links \mathcal{W} can be measured on different scales: *numerical* (age, weight, number of contacts), *ordinal* (level of education), and *nominal/categorical* (citizenship, sex, type of contact). They can be *input* as data or *computed* from the network.

They can be represented (using factorization) as a numerical vector $\mathbf{v} = [v_i]$.

Clustering – partition of elements (nodes/links) – *nominal* or *ordinal* data about elements

$v_i \in \mathbb{N}$: element i belongs to the cluster/group v_i ;

Vector – *numeric* data about elements

$v_i \in \mathbb{R}$: the property has value v_i on element i ;

Permutation – *ordering* of elements

$v_i \in \mathbb{N}$: element i is at the v_i -th position.

degree of node v , $\deg(v)$ = number of links with v as an endnode – a star;

indegree of node v , $\text{ideg}(v)$ = number of links with v as a terminal node – in instar (endnode is both initial and terminal);

outdegree of node v , $\text{odeg}(v)$ = number of links with v as an initial node – an outstar.

For a graph,

initial node $v \Leftrightarrow \text{ideg}(v) = 0$

terminal node $v \Leftrightarrow \text{odeg}(v) = 0$

$$n = 12, m = 23, \text{ideg}(e) = 3, \text{odeg}(e) = 5, \deg(e) = 6$$

$$\sum_{v \in V} \text{ideg}(v) = \sum_{v \in V} \text{odeg}(v) = |\mathcal{A}| + 2|\mathcal{E}| - |\mathcal{E}_0|, \quad \sum_{v \in V} \deg(v) = 2|\mathcal{L}| - |\mathcal{L}_0|$$

We will also use some additional notions:

$N(v)$ is the set of *neighbors* of node v – other endnodes of links containing the node v .

$iN(v)$ is the set of *in-neighbors* of node v – other nodes from which a link leads to the node v .

$oN(v)$ is the set of *out-neighbors* of node v – other nodes to which a link leads from the node v .

weighted in/out-degree (column/row sums)

$$\text{wd}(v) = \sum_{e \in \text{star}(v)} w(e)$$

$$\text{wid}(v) = \sum_{e \in \text{istar}(v)} w(e), \quad \text{wod}(v) = \sum_{e \in \text{ostar}(v)} w(e)$$

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

Numerical properties of nodes are represented by *vectors*, nominal properties by *partitions* or as *labels* of nodes. Numerical property can be displayed as *size* (width and height) of node (figure), as its *coordinate*; and a nominal property as *color* or *shape* of the figure, or as a node's *label* (content, size and color). Numerical values of links can be displayed as *value*, *thickness* or *grey level*. Nominal values can be assigned as *label*, *color* or *line pattern*.

Besides ordinary (directed, undirected, mixed) networks, some extended types of networks are also used:

- *2-mode networks*, bipartite (valued) graphs – networks between two disjoint sets of nodes $\mathcal{N} = ((\mathcal{U}, \mathcal{V}), \mathcal{L}, \mathcal{P}, \mathcal{W})$
- *multipartite networks* $\mathcal{N} = ((\mathcal{V}_1, \dots, \mathcal{V}_k), \mathcal{L}, \mathcal{P}, \mathcal{W})$
- *multirelational networks* $\mathcal{N} = (\mathcal{V}, (\mathcal{L}_1, \mathcal{L}_2, \dots, \mathcal{L}_k), \mathcal{P}, \mathcal{W})$
- *temporal networks*, dynamic graphs – networks changing over time $\mathcal{N}_T = (\mathcal{V}, \mathcal{L}, \mathcal{P}, \mathcal{W}, T)$
- *collections of networks* having some node sets in common
- specialized networks: representation of genealogies as *p-graphs*; *Petri's nets*, ...

Pictures in SVG: *66 days*. Kansas Event Data System *KEDS*

In a *two-mode* (affiliation or bipartite) network $\mathcal{UV} = ((U, V), L, uv)$, the set of nodes is split into two disjoint sets (*modes*) U and V . In this presentation, we will assume that the network is simple (no parallel links) and directed. Each arc $e \in L$ has its initial node in the set U and its terminal node in the set V . The function $w: L \rightarrow \mathbb{R}^+$ assigns to each arc its weight. In general, the weight can be measured on different measurement scales (counts, ratio, interval, ordinal, nominal, binary, TQ, etc.).

The network \mathcal{UV} can be represented with the corresponding *matrix* $\mathbf{UV} = [uv[u, v]]_{u \in U, v \in V}$ defined as

$$uv[u, v] = \begin{cases} w(u, v) & (u, v) \in L \\ \square & \text{otherwise} \end{cases}$$

We represent the number 0 with two symbols, 0 (weight 0) and \square (no link) where $\square = 0$ with rules $\square + a = a$ and $\square \cdot a = \square$.

The size of a network/graph is expressed by two numbers: number of nodes $n = |\mathcal{V}|$ and number of links $m = |\mathcal{L}|$.

In a *simple undirected* graph (no parallel edges, no loops) $m \leq \frac{1}{2}n(n-1)$; and in a *simple directed* graph (no parallel arcs) $m \leq n^2$.

Small networks (some tens of nodes) – can be represented by a picture and analyzed by many algorithms (*UCINET*, *NetMiner*).

Also *middle size* networks (some hundreds of nodes) can still be represented by a picture (!?), but some analytical procedures can't be used.

Till 1990, most networks were small. The advances in IT allowed the creation of networks from the data already available in the computer(s). *Large* networks became reality. Large networks are too big to be displayed in detail; special algorithms are needed for their analysis (*Pajek*).

Large networks

Weighted
networks 1

V. Batagelj

Large network – several thousands or millions of nodes. Can be stored in computer's memory – otherwise *huge* network. 64-bit computers!

Dunbar's number

Weighted
networks 1

V. Batagelj

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

Average degrees of the SNAP and Konect networks

Average degree $\bar{d} = \frac{1}{n} \sum_{v \in V} \deg(v) = \frac{2m}{n}$. Most real-life large networks are **sparse** – the number of nodes and links is of the same order. This property is also known as a **Dunbar's number**.

The basic idea is that if each node has to spend for each link certain amount of "energy" to maintain the links to selected other nodes, then, since it has a limited "energy" at its disposal, the number of links should be limited. In human networks the Dunbar's number is between 100 and 150.

Complexity of algorithms

Weighted
networks 1

V. Batagelj

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

Let us look to time complexities of some typical algorithms:

	$T(n)$	1.000	10.000	100.000	1.000.000	10.000.000
LinAlg	$O(n)$	0.00 s	0.015 s	0.17 s	2.22 s	22.2 s
LogAlg	$O(n \log n)$	0.00 s	0.06 s	0.98 s	14.4 s	2.8 m
SqrtAlg	$O(n\sqrt{n})$	0.01 s	0.32 s	10.0 s	5.27 m	2.78 h
SqrAlg	$O(n^2)$	0.07 s	7.50 s	12.5 m	20.8 h	86.8 d
CubAlg	$O(n^3)$	0.10 s	1.67 m	1.16 d	3.17 y	3.17 ky

For the interactive use on large graphs already quadratic algorithms, $O(n^2)$, are too slow.

Approaches to large networks

Weighted
networks 1

V. Batagelj

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

In the analysis of a *large* network (several thousands or millions of nodes, the network can be stored in computer memory) we can't display it in its totality; there are only a few algorithms available.

To analyze a large network, we can use a statistical approach or we can identify smaller (sub) networks that can be analyzed further using more sophisticated methods.

Important nodes and links in network

Weighted
networks 1

V. Batagelj

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

To identify important / interesting elements (nodes, links) in a network, we often try to express our intuition about important / interesting elements using an appropriate measure (index, weight) following the scheme

*The larger is the measured value of an element,
more important / interesting is this element*

Too often, in the analysis of networks, researchers uncritically pick some measures from the literature. For a formal approach, see [Roberts](#).

The (importance) measure can be obtained as input data – an *observed* property, or computed from the network description – a *structural* property.

An interesting question is studying associations among structural and observed properties. Can an observed property be explained with some structural property/ies?

Node indices

Weighted
networks 1

V. Batagelj

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

The most important distinction between different node *indices* is based on the view/decision of whether the network is considered directed or undirected.

Closeness, betweenness, clustering, eigen-vector, ...

A network is *weighted* iff $\mathcal{W} \neq \emptyset$.

Assume that the weight w in the network $\mathcal{N} = (V, L, w)$, $w : L \rightarrow \mathbb{R}$ is “compatible” with our research question:

*larger is the value of the weight $w(e) \Rightarrow$
more important is the link $e \in L$ with respect to our question*

To identify important nodes or subnetworks we can use: cuts, islands, (valued) cores, clustering (corrected dissimilarities), etc.

Using link cuts, islands, cores, skeletons (spanning tree, Pathfinder, k-neighbors), community detection, hubs and authorities, etc. we can identify the most active subnetworks. We can also apply clustering and blockmodeling methods. [?]

- 1 (directly) measured: road traffic, baboons, ...
- 2 derived – computed from existing data
 - 1 projections of two-mode networks
 - 2 network weight indexes: SPC weights, preferential attachment, $w(u : v) = \deg(u) \cdot \deg(v)$, link betweenness, short cycles counts; (dis)similarity between end-nodes
- 3 structured values, signed networks → semirings

sparse, threshold, only for links of a given network

Important links – Weighted networks

Weighted networks 1

V. Batagelj

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

A very important characteristic of weight is its nature – should it be considered a *similarity* (larger is the link weight more similar are its end-nodes) or a *dissimilarity* (larger is the link weight more different are its end-nodes; weight for links with equal end-nodes is usually 0)?

Structural weights are computed based on the network structure. For example

$$w(e(u, v)) = \deg(u) \cdot \deg(v)$$

More substantial weights exist.

Triangular network

Weighted
networks 1

V. Batagelj

Introduction

Networks

Properties

Large
networks

Weighted
networks

References

Let \mathcal{G} be a simple undirected graph. A **triangular network** $\mathcal{N}_T(\mathcal{G}) = (\mathcal{V}, \mathcal{E}_T, w)$ determined by \mathcal{G} is a subgraph $\mathcal{G}_T = (\mathcal{V}, \mathcal{E}_T)$ of \mathcal{G} which set of edges \mathcal{E}_T consists of all triangular edges of $\mathcal{E}(\mathcal{G})$. For $e \in \mathcal{E}_T$ the weight $w(e)$ equals to the number of different triangles in \mathcal{G} to which e belongs. Triangular networks can be used to efficiently identify dense clique-like parts of a graph. If an edge e belongs to a k -clique in \mathcal{G} then $w(e) \geq k - 2$.

If a graph \mathcal{G} is mixed, we replace edges with pairs of opposite arcs. Let $\mathcal{G} = (\mathcal{V}, \mathcal{A})$ be a simple directed graph without loops. For a selected arc $(u, v) \in \mathcal{A}$ there are only two different types of directed triangles: **cyclic** and **transitive**.

The standard approach to finding interesting groups inside a network is based on properties/weights.

The **node-cut** of a network $\mathcal{N} = (\mathcal{V}, \mathcal{L}, p)$, $p : \mathcal{V} \rightarrow \mathbb{R}$, at selected level t is a subnetwork $\mathcal{N}(t) = (\mathcal{V}', \mathcal{L}(\mathcal{V}'), p)$, determined by the set

$$\mathcal{V}' = \{v \in \mathcal{V} : p(v) \geq t\}$$

and $\mathcal{L}(\mathcal{V}')$ is the set of links from \mathcal{L} that have both endnodes in \mathcal{V}' .

The **link-cut** of a network $\mathcal{N} = (\mathcal{V}, \mathcal{L}, w)$, $w : \mathcal{L} \rightarrow \mathbb{R}$, at selected level t is a subnetwork $\mathcal{N}(t) = (\mathcal{V}(\mathcal{L}'), \mathcal{L}', w)$, determined by the set

$$\mathcal{L}' = \{e \in \mathcal{L} : w(e) \geq t\}$$

and $\mathcal{V}(\mathcal{L}')$ is the set of all endnodes of the links from \mathcal{L}' .

netsWeight

Large
networks

Weighted
networks

References

I started to develop an R package `netsWeight` over `igraph`, extending its capabilities with some tools for analysis of weighted networks. The package `netsWeight` contains functions

`interlinks(N, atn, c1, c2, col1="red", col2="blue")` – extracts from a given network N , a subnetwork determined by node clusters C_1 and C_2 , and links between them. C_i is the set of nodes having for the attribute with name atn the value c_i . Its nodes have color col_i .

`node_cut(N, atn, t)` – node cut in N for the node property atn at threshold t .

`link_cut(N, atn, t)` – link cut in N for the link property atn at threshold t .

The threshold value t is determined based on the distribution of values of weight w or property p . Usually, we are interested in cuts that are not too large, but also not trivial.

Normalizations

In networks obtained from large two-mode networks, there are often huge differences in weights. Therefore, it is not interesting to compare the nodes according to the raw data – the nodes/links with large values will prevail. First, we have to *normalize* the network to make the weights comparable.

Markov (also known as stochastic, affinity, output, row)
normalization: For $\text{wod}(u) > 0$

$$w_M(u, v) = \frac{w(u, v)}{\text{wod}(u)}$$

If $\text{wod}(u) = 0$ also $w_M(u, v) = 0$.

Jaccard-like normalization:

$$w_J(u, v) = \frac{w(u, v)}{\text{wod}(u) + \text{wod}(v) - w(u, v)}$$

Salton-like normalization:

$$w_S(u, v) = \frac{w(u, v)}{\sqrt{\text{wod}(u) \cdot \text{wod}(v)}}$$

Balassa or activity normalization [Matveeva et al.(2023)]: Let $T = \sum_{u,v} w(u, v)$ be the total sum of weights in the network.

$$w_A(u, v) = \frac{w(u, v) \cdot T}{\text{wod}(u) \cdot \text{wid}(v)}$$

If $w_A(u, v) > 1$, the measured weight is larger than expected.

A symmetric version

$$w_B(u, v) = \log_2 w_A(u, v) \quad \text{for } w_A(u, v) > 0$$

For a square matrix with nonzero diagonal values $\mathbf{C} = [c[u, v]]$
[Batagelj and Mrvar(2003)]

$$c_{\min}[u, v] = \frac{c[u, v]}{\min(c[u, u], c[v, v])} \quad c_{\max}[u, v] = \frac{c[u, v]}{\max(c[u, u], c[v, v])}$$

$$c_{\min\text{Dir}}[u, v] = \begin{cases} \frac{c[u, v]}{c[u, u]} & c[u, u] \leq c[v, v] \\ 0 & \text{otherwise} \end{cases}$$

$$c_{\max\text{Dir}}[u, v] = \begin{cases} \frac{c[u, v]}{c[v, v]} & c[u, u] \leq c[v, v] \\ 0 & \text{otherwise} \end{cases}$$

After a selected normalization, the important parts of the network are obtained by link-cuts or islands approaches.

A book on **Statistical Analysis of Network Data with R** using the package igraph was written by Kolaczyk, Eric D. and Csárdi, Gábor (Springer 2014).

Another book on igraph is prepared by Gábor Csárdi, Tamás Nepusz, and Edoardo M. Airolidi **draft**.

igraph can be installed from CRAN

<https://cran.r-project.org/web/packages/igraph/index.html>
