We will discuss some approaches to **exploratory analysis** of weighted dense temporal networks of moderate size. For illustration, we use world trade data.

WTO and UN comtrade and some other institutions are collecting world trade data. The problem with the collected data is missing data and inconsistencies.

An early version of world trade flows was provided by NBER ([Feenstra et al.(2005)]; [download](#)).

The French research center CEPII is providing a consolidated version of the UN comtrade data as a database [BACI/CEPII](#) [Gaulier and Zignago(2010)].

An application of the network analysis to the BACI data was done already by de Benedictis et al.

[[De Benedictis et al.\(2014\)](#), [Hoang et al.\(2023\)](#)].

BACI data

World trade
datasets

Matrix layout

Skeletons

Normalizations

Conclusions

References

Each BACI trade flow is described by 6 quantities:

- Year,
- Product category (HS 6-digit code),
- Exporter (ISO 3-digit country code),
- Importer (ISO 3-digit country code),
- Value of the trade flow (in thousands current USD),
- Quantity (in metric tons)

HS codes: [Harmonized Commodity Description and Coding Systems \(HS\)](#), [Classifications on economic statistics](#), [Harmonized System Codes \(HS Code 2017 - Current\)](#).

Currently, there are around 5300 different HS codes. They are hierarchically organized. The 97 2-digit codes are also called *chapters*. They are joined into 21 *sections*. This enables the user to study the data at different granularity levels. In this presentation, we will limit our attention to the top level – the total trade flow values between countries in a year.

Weighted temporal multi-relational network

Conclusions

References

The BACI data essentially determine a *weighted temporal multi-relational network* $\mathcal{N} = (\mathcal{V}, (\mathcal{L}_h)_{h \in HS}, w, \mathcal{T})$ where \mathcal{V} is the set of world countries, relation \mathcal{L}_h is the set of links with the HS code h , $w : \mathcal{L} \rightarrow \mathbb{R}^+$ is the flow value (in thousands current USD), and $\mathcal{T} = 1996 : 2023$ is the observed range of years.

In a temporal network, nodes $v \in \mathcal{V}$ and links $e \in \mathcal{L}$ are not necessarily present or active in all time points. Let $T(v)$ be the *activity set* of time points for node v and $T(e)$ the activity set of time points for link $e \in \mathcal{L}$. Besides the presence/absence of nodes and links also their properties can change through time – the weight w becomes a *temporal quantity* [Batagelj and Praprotnik(2016)]

$$w(t) = \begin{cases} w'(t) & t \in T(w) \\ \text{\#} & t \in \mathcal{T} \setminus T(w) \end{cases}$$

where $T(w)$ is the *activity time set* of w , $w'(t)$ is the value of w in an instant $t \in T(w)$, and \# denotes the value *undefined*.

Weighted temporal multi-relational network

A *time slice* of \mathcal{N} in an instant $t \in \mathcal{T}$ is called the network $\mathcal{N}(t) = (\mathcal{V}(t), \mathcal{L}(t), w(t))$ where $\mathcal{V}(t) = \{v \in \mathcal{V} : t \in T(v)\}$ and $\mathcal{L}(t) = \{e \in \mathcal{L} : t \in T(e)\}$.

They can also be considered weighted multiway network data on four sets of nodes: Exporters, Importers, HS codes, and Years, with the flow value as a weight.

We converted the BACI data into Pajek format at the total, section, and chapter levels ([to Pajek](#), [GitHub](#)).

In this presentation, we limit our attention to **time slices** of the **totally aggregated network**.

- Larger, $n > 20$, dense graphs can't be presented readably with a graphical layout. For WT2023 the number of nodes is $n = 226$ and the density $\gamma = 0.6068$. For dense graphs of moderate size (up to some hundreds of nodes), a better option is the matrix representation.
- What about weights? They can be represented by link thickness or levels of grey of matrix cells. The problem is a very large range and the distribution of weights – most weights give almost white cells. For WT2023 $w_{\min} = 0.001$ and $w_{\max} = 456484584$. Monotonic transformations such as $w' = a \cdot w$, $a > 0$ or $w' = \sqrt{w}$ or $w' = \log(w)$, etc. In our case, we used $w' = (1000 \cdot w)^{0.08}$.
- A better ordering of rows can be obtained by network clustering [Batagelj et al.(2014)]. Additional reordering of subtrees can be made manually using Pajek by reordering nodes in the hierarchy.

Conclusions

References

To get insight into the structure of a large network we can reduce it to its skeleton by removing less important links and/or nodes [Batagelj (2011)].

- Most often the spanning tree, link cut, or node cut are used.
- In the closest k -neighbor skeleton for each node only the largest k incident links are preserved. Invariant for monotonic transformations.
- The Pathfinder algorithm was proposed in the 1980s by Schvaneveldt [Schvaneveldt et al.(1988), Schvaneveldt(1990), Batagelj et al.(2014)]. It removes from the network with a dissimilarity weight all links that do not satisfy the triangle inequality – if a shorter path exists that connects the link's end-nodes then the link is removed.
- Cores are a very efficient tool to determine the most cohesive (active) subnetworks [2]. The subset of nodes $\mathbf{C} \subseteq \mathcal{V}$ induces a P_s core at level t if for all $v \in \mathbf{C}$ it holds $w\deg_{\mathbf{C}}(v) \geq t$, and \mathbf{C} is the maximum such subset.

In networks with weights with a large range usually a few strong nodes prevail. To diminish or neutralize the influence of size on results different normalizations were proposed and used [Batagelj and Mrvar(2003), Matveeva et al.(2023)].

Let $T = \sum_{e \in \mathcal{L}} w(e)$ and for $(u, v) \in \mathcal{L}$ (Balassa index)

$$A(u, v) = \frac{w[u, v] \cdot T}{\text{woutdeg}(u) \cdot \text{windeg}(v)}$$

then the *activity normalization* w'

$$w'(u, v) = \log_2 A(u, v)$$

- BACI is a gold mine.
- Margin labels in large matrices are not very handy – SVG/JS support with tooltips.
- We intend to look at the data also as a multiway network.
